Linear Mathematical Modeling Examples with Answers

Linear mathematical modeling involves creating models where relationships between variables are

expressed as linear equations. These models are widely used due to their simplicity and ease of interpretation. Linear models often arise in situations where changes in one variable cause proportional changes in another. This section presents common linear modeling examples along with detailed answers to illustrate both the formulation and solution processes.

Example 1: Cost and Revenue Model

Consider a company that produces gadgets. The fixed cost is \$5000, and the cost to produce one gadget is \$20. The company sells each gadget for \$50. The goal is to model the profit as a function of the number of gadgets sold.

Solution: Let x represent the number of gadgets sold. The total cost $C(x)$ is given by:

- $C(x) = 5000 + 20x$ (fixed cost plus variable cost)

The total revenue $R(x)$ is:

- $R(x) = 50x$

The profit $P(x)$ is revenue minus cost:

- $P(x) = R(x) - C(x) = 50x - (5000 + 20x) = 30x - 5000$

This linear model allows the company to predict profit for any number of gadgets sold.

Example 2: Distance–Speed–Time Relationship

A car travels at a constant speed of 60 miles per hour. The distance traveled d after t hours can be modeled linearly.

Solution: The relationship is:

- $d = 60t$

This simple linear model expresses distance as a function of time, assuming constant speed.

Nonlinear Mathematical Modeling Examples with Answers

Nonlinear mathematical modeling addresses situations where relationships between variables are not proportional or linear. These models include quadratic, exponential, logarithmic, and other complex forms. Nonlinear models often capture more realistic behaviors in natural and social systems. This section discusses several nonlinear examples with solutions to demonstrate their construction and analysis.

Example 3: Population Growth Model (Exponential)

A population of bacteria doubles every hour. Starting with 100 bacteria, model the population size after t hours.

Solution: The population $P(t)$ follows exponential growth:

- $P(t) = 100 \times 2^t$

This nonlinear model shows how the population increases exponentially over time.

Example 4: Projectile Motion

A ball is thrown vertically upward with an initial velocity of 40 feet per second from a height of 5 feet.

The height $h(t)$ after t seconds is modeled by the quadratic equation:

- $h(t) = -16t^2 + 40t + 5$

Solution: This nonlinear model accounts for gravity's acceleration. For example, to find the height after 2 seconds, substitute $t=2$:

- $h(2) = -16(2)^2 + 40(2) + 5 = -64 + 80 + 5 = 21$ feet

Discrete Mathematical Modeling Examples with Answers

Discrete mathematical modeling deals with systems where variables change at distinct, separate points in time or space. Such models are essential in computer science, operations research, and decision-making processes. This section includes examples of discrete models, illustrating how to formulate and solve problems involving sequences, difference equations, and combinatorial structures.

Example 5: Fibonacci Sequence Model

The Fibonacci sequence is defined by the recurrence relation $F(n) = F(n-1) + F(n-2)$ with initial values $F(0) = 0$ and $F(1) = 1$. Find $F(6)$.

Solution: Calculate stepwise:

- $F(2) = 1$

- $F(3) = 2$

- $F(4) = 3$

- $F(5) = 5$

- $F(6) = 8$

This discrete model is widely used to model population growth, financial markets, and algorithmic processes.

Example 6: Inventory Management

A store starts with 100 units of a product and sells 15 units weekly. Model the inventory level after n weeks.

Solution: The inventory $I(n)$ after n weeks is given by:

- $I(n) = 100 - 15n$

This discrete linear model helps plan restocking schedules to avoid shortages.

Continuous Mathematical Modeling Examples with Answers

Continuous mathematical modeling applies to scenarios where variables change continuously over time or space, often described by differential equations. These models are fundamental in physics, engineering, and natural sciences. The following examples demonstrate continuous modeling techniques along with thorough solutions.

Example 7: Cooling of an Object (Newton's Law of Cooling)

An object initially at 90°C cools in a room at 20°C . The temperature $T(t)$ after t minutes follows the differential equation:

- $dT/dt = -k(T - 20)$

If $k = 0.1$, find T after 10 minutes given $T(0) = 90$.

Solution: The solution is:

- $T(t) = 20 + (90 - 20)e^{-0.1t}$

Calculate $T(10)$:

- $T(10) = 20 + 70e^{-1} \approx 20 + 70 \times 0.3679 \approx 45.75^\circ\text{C}$

Example 8: Logistic Growth Model

A population grows according to the logistic equation:

- $dP/dt = rP(1 - P/K)$

where $r = 0.5$ (growth rate) and $K = 1000$ (carrying capacity). If initial population $P(0) = 100$, find the population at time t using the logistic model.

Solution: The logistic growth function is:

- $P(t) = K / (1 + ((K - P(0))/P(0))e^{-rt})$

Substitute values:

- $P(t) = 1000 / (1 + 9e^{-0.5t})$

This continuous nonlinear model effectively describes constrained population growth.

mathematical modeling examples with answers: *Mathematical Models in Population Biology and Epidemiology* Fred Brauer, Carlos Castillo-Chavez, 2013-03-09 As the world population exceeds the six billion mark, questions of population explosion, of how many people the earth can support and under which conditions, become pressing. Some of the questions and challenges raised can be

addressed through the use of mathematical models, but not all. The goal of this book is to search for a balance between simple and analyzable models and unsolvable models which are capable of addressing important questions such as these. Part I focusses on single-species simple models including those which have been used to predict the growth of human and animal population in the past. Single population models are, in some sense, the building blocks of more realistic models - the subject of Part II. Their role is fundamental to the study of ecological and demographic processes including the role of population structure and spatial heterogeneity - the subject of Part III. This book, which includes both examples and exercises, will be useful to practitioners, graduate students, and scientists working in the field.

mathematical modeling examples with answers: Biomathematical Modeling Olcay Akman, Christopher Hay-Jahans, 2025-05-19 Welcome to the fascinating intersection of mathematics, biology, and ecology! This book is intended primarily as a resource for teachers planning to teach their first introductory course on modeling in mathematical biology and/or ecology. This being said, it can also be used by students preparing to embark on an independent studies project in one of these fields; or, by researchers unfamiliar with the methods or software introduced who are seeking an accessible and quick introduction to one of the methods and/or software presented here; or, by curious biologists, ecologists, or mathematicians who may be unfamiliar with the other side; or, maybe, by the perpetual learner who is intrigued by the dynamics of living ecosystems. For each of the above, this book is designed to be an accessible introduction to the captivating landscape of biomathematics. The approach used in this book takes advantage of technology in leading readers on a journey that bridges seemingly distinct fields through introductions to three methods and software platforms: Compartmental models with Berkeley Madonna; agent-based models with NetLogo; and cluster analysis through selforganizing maps using an R Shiny app. This is not intended to be a textbook (though it may be used as one), nor is it a purely mathematics book or one purely about deeper aspects of biology or ecology. It focuses on three selected ways in which the intersection of mathematics and biology (and mathematics and ecology) can be explored with the help of software. Moreover, the manner in which the content is presented makes it possible to use this book to help prepare for an introductory course at a wide range of levels, depending on the discipline within which the course is taught and the mathematical prerequisites for the course. There are four chapters, the first of which presents the reader with a bit of background information followed by suggestions on how to get the most out of this book. The three core chapters introduce the three previously mentioned methods and software in a manner envisioned to be accessible to most.

mathematical modeling examples with answers: Facets of Systems Science George J. Klir, 2012-12-06 This book has a rather strange history. It began in spring 1989, thirteen years after our Systems Science Department at SUNY-Binghamton was established, when I was asked by a group of students in our doctoral program to have a meeting with them. The spokesman of the group, Cliff Joslyn, opened our meeting by stating its purpose. I can closely paraphrase what he said: We called this meeting to discuss with you, as Chairman of the Department, a fundamental problem with our systems science curriculum. In general, we consider it a good curriculum: we learn a lot of concepts, principles, and methodological tools, mathematical, computational, heuristic, which are fundamental to understanding and dealing with systems. And, yet, we learn virtually nothing about systems science itself. What is systems science? What are its historical roots? What are its aims? Where does it stand and where is it likely to go? These are pressing questions to us. After all, aren't we supposed to carry the systems science flag after we graduate from this program? We feel that a broad introductory course to systems science is urgently needed in the curriculum. Do you agree with this assessment? The answer was obvious and, yet, not easy to give: I agree, of course, but I do not see how the situation could be alleviated in the foreseeable future.
