mathematical methods in the physical sciences by boas: Mathematics for the Physical Sciences James B. Seaborn, 2012-12-06 This book is intended to provide a mathematical bridge from a general physics course to intermediate-level courses in classical mechanics, electricity and magnetism, and quantum mechanics. The book begins with a short review of a few topics that should be familiar to the student from a general physics course. These examples will be used throughout the rest of the book to provide physical contexts for introducing the mathematical applications. The next two chapters are devoted to making the student familiar with vector operations in algebra and calculus. Students will have already become acquainted with vectors in the general physics course. The notion of magnetic flux provides a physical connection with the integral theorems of vector calculus. A very short chapter on complex numbers is sufficient to supply the needed background for the minor role played by complex numbers in the remainder of the text. Mathematical applications in intermediate and advanced undergraduate courses in physics are often in the form of ordinary or partial differential equations. Ordinary differential equations are

introduced in Chapter 5. The ubiquitous simple harmonic oscillator is used to illustrate the series method of solving an ordinary, linear, second-order differential equation. The one-dimensional, time-dependent Schrödinger equation provides an illustration for solving a partial differential equation by the method of separation of variables in Chapter 6.

mathematical methods in the physical sciences by boas: Partial Differential Equations for Mathematical Physicists Bijan Kumar Bagchi, 2019-07-02 Partial Differential Equations for Mathematical Physicists is intended for graduate students, researchers of theoretical physics and applied mathematics, and professionals who want to take a course in partial differential equations. This book offers the essentials of the subject with the prerequisite being only an elementary knowledge of introductory calculus, ordinary differential equations, and certain aspects of classical

mechanics. We have stressed more the methodologies of partial differential equations and how they can be implemented as tools for extracting their solutions rather than dwelling on the foundational aspects. After covering some basic material, the book proceeds to focus mostly on the three main types of second order linear equations, namely those belonging to the elliptic, hyperbolic, and parabolic classes. For such equations a detailed treatment is given of the derivation of Green's functions, and of the roles of characteristics and techniques required in handling the solutions with the expected amount of rigor. In this regard we have discussed at length the method of separation variables, application of Green's function technique, and employment of Fourier and Laplace's transforms. Also collected in the appendices are some useful results from the Dirac delta function, Fourier transform, and Laplace transform meant to be used as supplementary materials to the text. A good number of problems is worked out and an equally large number of exercises has been appended at the end of each chapter keeping in mind the needs of the students. It is expected that this book will provide a systematic and unitary coverage of the basics of partial differential equations. Key Features An adequate and substantive exposition of the subject. Covers a wide range of important topics. Maintains mathematical rigor throughout. Organizes materials in a self-contained way with each chapter ending with a summary. Contains a large number of worked out problems.
